Package bounddvi v7.0

Koichi Inoue & Hironobu Yamashita

2016/10/24

Package bounddvi sets papersize special into DVI file. This package can be used in both tate (vertical) and yoko (horizontal) writing directions of Japanese pLaTeX/upLaTeX, and both `dvipdfmx` and `dvips` drivers are supported. The `tombow` option defined in Japanese pLaTeX kernel is also supported. Of course, this package can be used also with the original LaTeX in DVI output mode.

This package is part of platex-tools bundle:

`https://github.com/aminophen/platex-tools`

Usage

Load this package in preamble.

```
\documentclass[a5paper]{article}
\usepackage{bounddvi}
...
```

Process the `.tex` file using `latex` + `dvips` chain or `latex` + `dvipdfmx` chain.

Known limitations

1. The compatibility with geometry package may not be perfect. When `dvips` is used, the specification which appears *first* in DVI takes effect. On the other hand, when `dvipdfmx` is used, the specification which appears *at last* in DVI takes effect. For this reason,

   ```
   % latex + dvipdfmx
   \documentclass{...}
   \usepackage{bounddvi}
   \usepackage[dvipdfm]{geometry}
   ```

   can sometimes fail to set proper paper size.

2. This package supports "jsclasses-like employment" of `\mag`, because it's more widely used in Japan. This may be incompatible with some classes or packages which employ `\mag` in other ways (see descriptions below).

Note about \mag handling

Among the packages in CTAN, there are two types of implementation in terms of `\mag` employment. It seems that there is no (official or practical) "standard" in `\mag` treatment.

When the output is going to the physical size of A4 (210 mm × 297 mm), there are two ways: some classes/packages can set

> `\mag=2000`
> `\paperwidth=210mm` (= 420 truemm)
> `\paperheight=297mm` (= 594 truemm)

and others can set

> `\mag=2000`
> `\paperwidth=105mm` (= 210 truemm)
> `\paperheight=148.5mm` (= 297 truemm)

The first way is adopted by geometry package etc, and it's (probably) based on the behavior of the `papersize` special of `dvips`. It does not handle true units properly, and accepts only non-true units and evaluates them as if they were true units. The second way is adopted by jsclasses document class etc, and is also suppoted by `pdf:pagesize` special of `dvipdfm(x)`. This can be more consistent with LaTeX, since all other layout parameters (e.g. `\textwidth`) are set according to the unit truemm.

The bounddvi supports the latter, so some classes/packages which are based on the former may or may not work properly when using bounddvi package.

ChangeLog

- 2002/03/10 v1.0 (KI) First version
- 2002/10/30 v2.0 (KI) Add dvipdfm pdf:pagesize special
- 2003/03/22 v3.2 (KI) Compatibility with hyperref
- 2004/05/08 v4.0 (KI) Support for `\mag` $\neq$ 1000
- 2004/12/08 v5.2 (KI) Compatibility with geometry
- 2004/12/15 v6.0 (KI) Not to use dvipdfm(x) pdf:pagesize special
- 2016/10/24 v7.0 (HY) Support for pLaTeX 2_ε tombow option, compatibility with graphics/color packages
